Prof. Csernátony-Hoffer András BME

„Regular Member of CIGRE SC 15”

1979-ig ezen a területen dolgozott

Szponzorok: NIM, OMFB, MVMT.

tgδ: Dielectric dissipation factor measured at constant voltage, $tg\delta(f;T;X)$ means "loss factor" , was measured in function of frequency (f), temperature (T) and moisture content in the paper (X).

C: Capacitance at constant voltage, $C(f;T;X)$, means the capacitance, was measured in function of frequency (f), temperature (T) and moisture content in the paper (X).

**The Initial slope of recovery voltage: $S_R(t_C/t_D;T;X)$
and**

The peak of the recovery voltage: $U_R \max(t_C/t_D;T;X;T;X)$

The temperature with 6 equally spaced values between 25°C and 90°C (25, 38, 51, 64, 77 and 90°C), the moisture content of the cellulose with 5 values between 0.5% and 4% (0,5, 1, 2, 3 and 4 %), served as parameters in all of these measurements.

Where frequency was a variable parameter (tg/C or FDS), 8 meas. were taken between 0.05Hz and 50 Hz.

Where voltage was a variable parameter, 8 meas. between 6V and 1400V at 50 Hz were taken for AC tests and 8 measurements at values from 5V to 1000V were taken for DC tests.

RVM were taken at charge and discharge times between 0.02s/0.01s and 1000s/500s (following the series 2; 5; 10).

To investigate the influence of aging of the oil three different aged oils were used for impregnation:

new (Pt:lp/01: $\text{tg}\delta = 0,01\%$ or $10^4\text{tg}\delta = 100$ at 90°C),

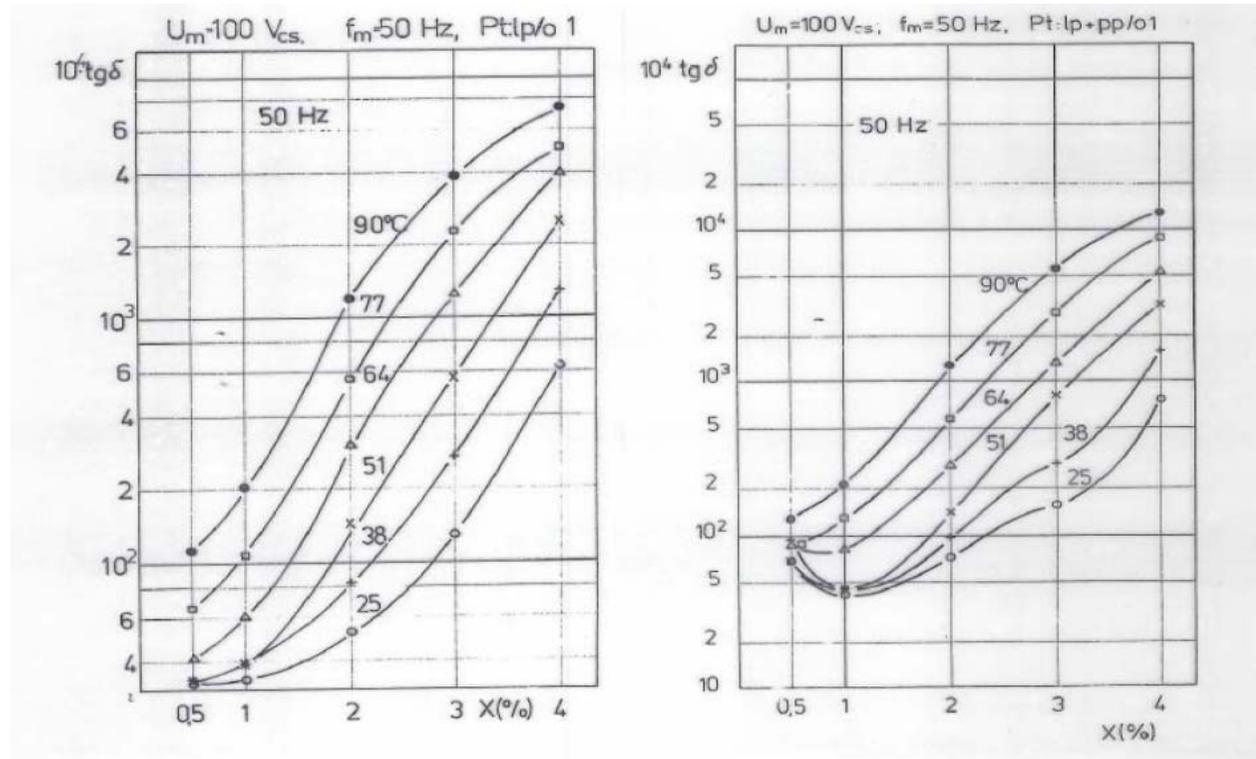

moderately aged (Pt:lp/02: $\text{tg}\delta = 0,1\%$ or $10^4\text{tg}\delta = 1000$ at 90°C),

and

heavily aged (Pt:lp/03: $0.5\% \leq \tan(\delta) \leq 0.7\%$ or $10^4\text{tg}\delta = 5000-7000$ at 90°C).

In the figures, the marking of samples with oil ducts was **Pt:lp+pp**, and without oil gap (only layered soft paper, without oil duct), the marking of samples was **Pt:lp**.

The $\text{tg}\delta_{50\text{Hz}}$ curves strongly depend on the temperature and moisture content decreasing sensitivity with decreasing moisture content.

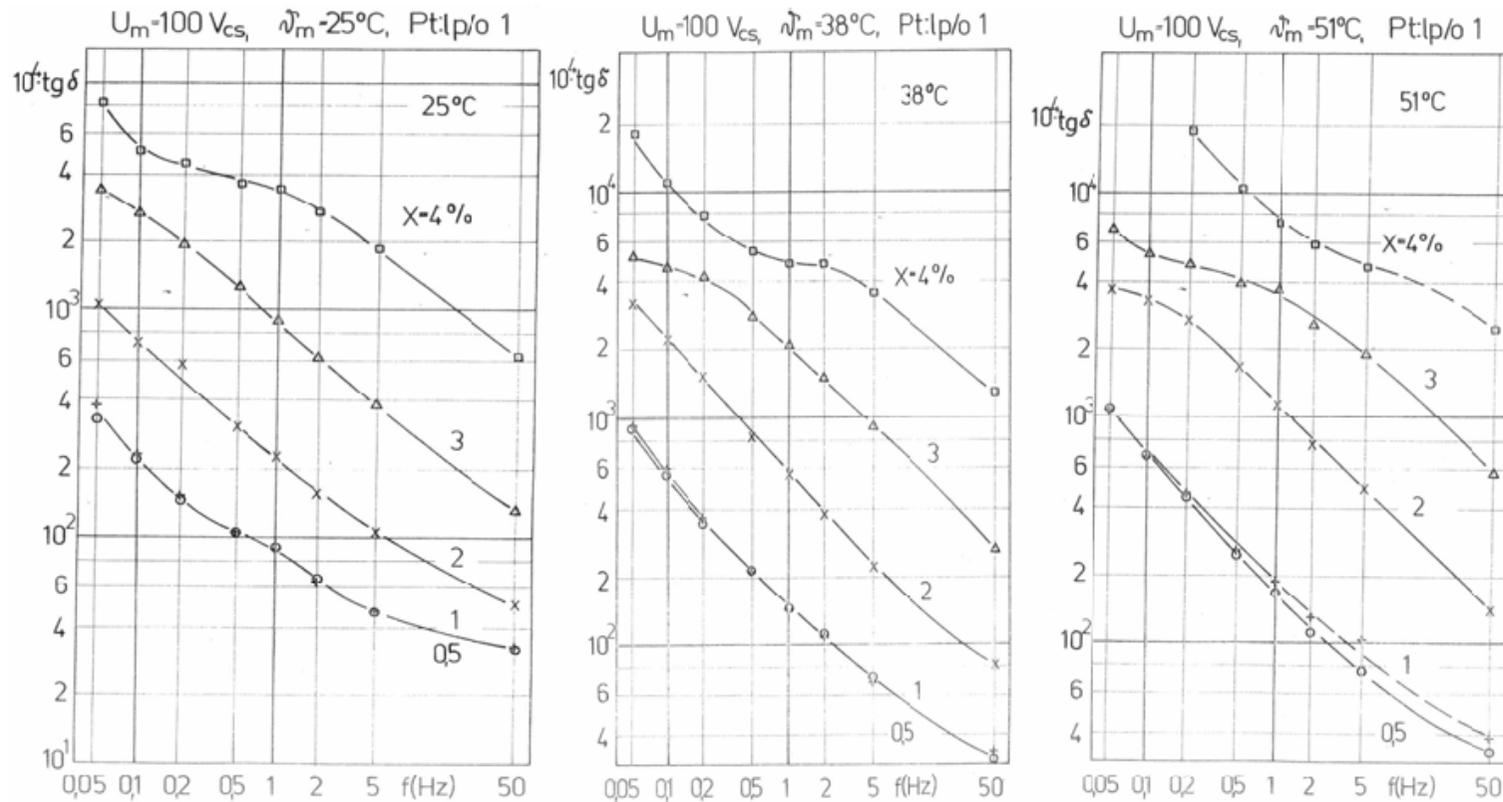

$10^4 \text{tg}\delta_{50\text{Hz}}(U;T;X)$: dielectric dissipation factor at 50 Hz,

Pt:lp/01: new paper, new oil $\text{tg}\delta \sim 0,01\%$ at 90°C without oil duct,

Pt:lp+pp/01 with oil duct.

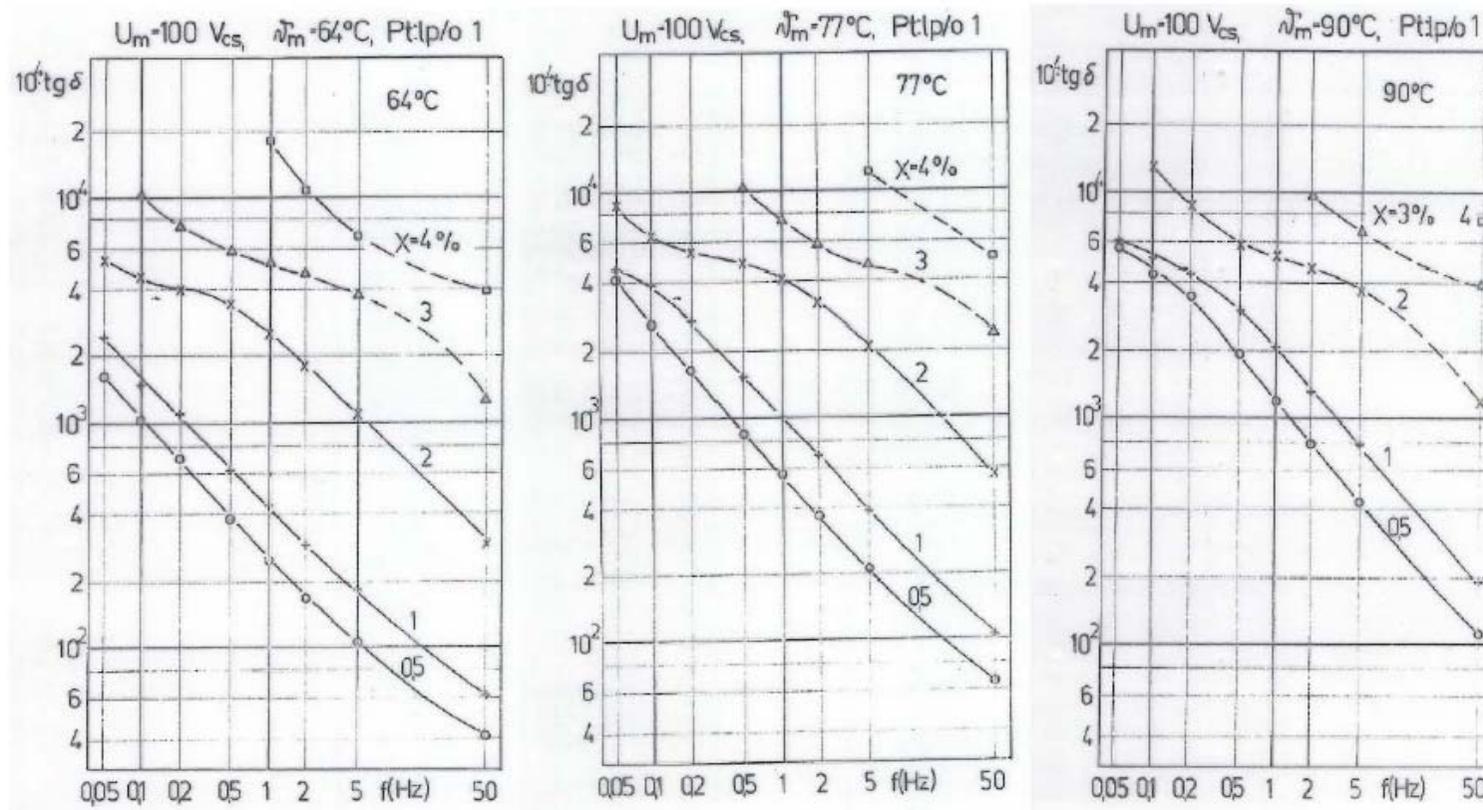

Moisture content in the paper from $X=0,5\%$ to 4% , temperature between 25°C - 90°C .

$\text{tg}\delta(f)$ curves show something like a local maximum inflection point, which moves toward higher frequencies with increasing moisture content and temperature.

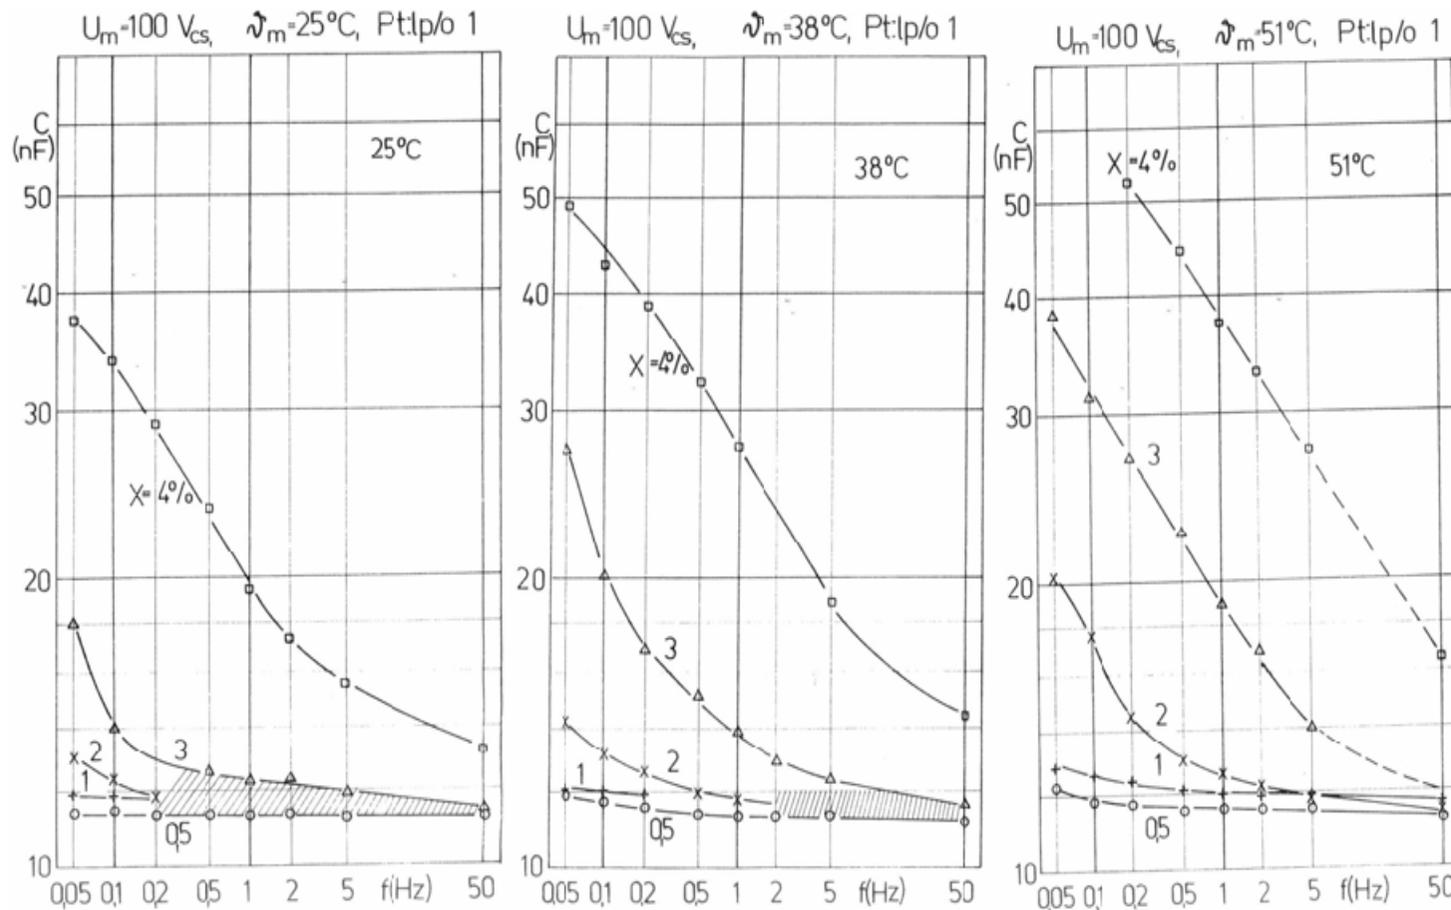

$\text{tg} \delta(f;T;X)$: Dielectric dissipation factor measured at constant voltage: It means "loss factor" as a function of frequency (f), moisture content (X) dependence at temperature (T) of 25°C, 38°C and 51°C.

$\text{tg}\delta(f)$ curves show something like a local maximum inflection point, which moves toward higher frequencies with increasing moisture content and temperature.

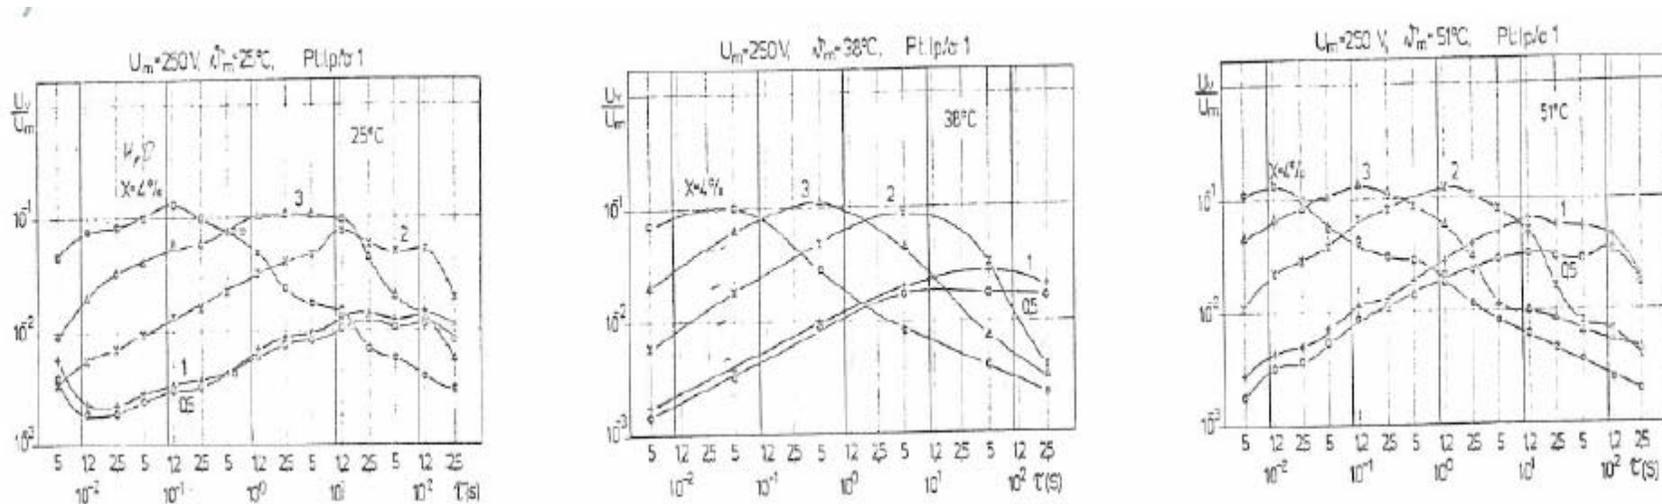

$\text{tg } \delta(f;T;X)$: Dielectric dissipation factor measured at constant voltage,
 Loss factor as function of frequency (f), moisture content (X) dependence at
 temperature (T) of 64°C, 77°C and 90°C.

C(f;T;X), capacitance at constant voltage as a function of frequency

C(f;T;X), capacitance at constant voltage as a function of frequency (f): moisture content (X) dependence, at temperature (T) of 25°C, 38°C and 51°C

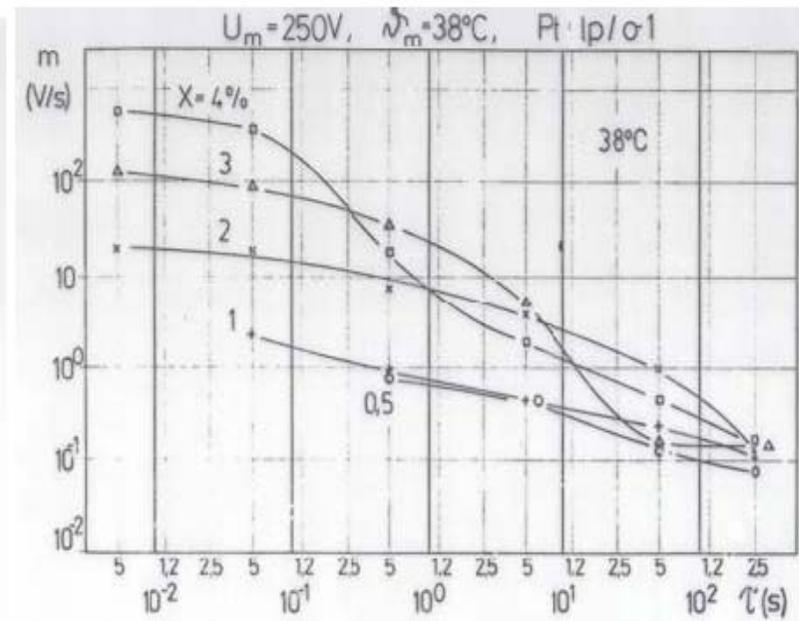

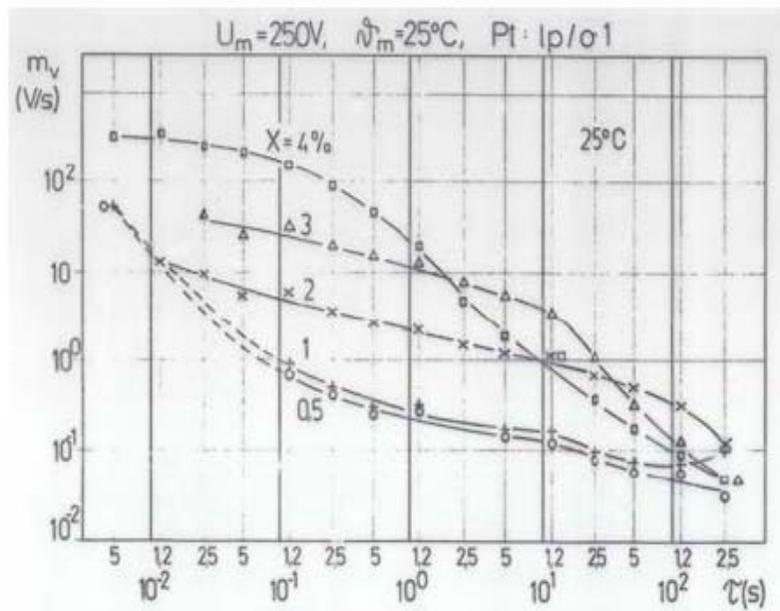

Maximum of the recovery voltage: $U_R \max(t_C/t_D; T; X)$ as a function of charge/discharge times (t_C/t_D), temperature (T) and moisture content (X).

$U_R \max(t_C/t_D; T; X)$, maximum of the recovery voltage, the function of charge//discharge times (t_C/t_D). The curves show the moisture content (X) dependence, the temperature (T) from 25°C to 51°C.

$U_R \max(t_C/t_D; T; X)$ figures show examples of the recovery voltage maxima expressed as relative values normalized to charge voltage as a function of charge time with moisture content as a parameter. The discharge time is always half of the discharge time. The location of the maximum depend on the temperature, the moisture content and the level of other aging products (model Pt:lp/01 means new paper/new oil).

Polarizációs spektrum módszerek

$S_R(t_C/t_D; T; X)$ the initial slopes of recovery voltage as a function of charge charge/discharge times (t_C/t_D). The curves show the moisture content (X) dependence, at the temperature (T) $25^\circ C$ and $38^\circ C$.
